Beyond Lebesgue and Baire IV:
Density topologies and a converse Steinhaus-Weil Theorem
by
N. H. Bingham and A. J. Ostaszewski

On the centenary of Hausdorff’s Mengenlehre (1914) and Denjoy’s
Approximate continuity (1915)

Abstract.
The theme here is category-measure duality, in the context of a topological group. One can often handle the (Baire) category case and the (Lebesgue, or Haar) measure cases together, by working bi-topologically: switching between the original topology and a suitable refinement (a density topology). This prompts a systematic study of such density topologies, and the corresponding $\sigma$-ideals of negligibles. Such ideas go back to Weil’s classic book, and to Hashimoto’s ideal topologies. We make use of group norms, which cast light on the interplay between the group and measure structures. The Steinhaus-Weil interior-points theorem (‘on $AA^{-1}$’) plays a crucial role here; so too does its converse, the Simmons-Mospan theorem.

Key words. Steinhaus-Weil property, Weil topology, shift-compact, density topology, Hashimoto ideal topology, group norm

Mathematics Subject Classification (2000): Primary 26A03; 39B62.

1 Introduction

This paper originates from several sources. The first three are our earlier studies ‘Beyond Lebesgue and Baire I-III’ ([BinO1,2], [Ost3]), the general theme of which is the similarity (indeed, duality) between measure and category, and the primacy of category/topology over measure in many areas. The second three are recent studies by the second author on the Effros Open Mapping Principle ([Ost4,5,6]; §6.4 below).

The Steinhaus-Weil property (critical for regular variation; see [BinGT, Th. 1.1.1]) of a set $S$ in a topological group $G$, that $1_G$ is an interior point of $SS^{-1}$ when $S$ is non-negligible (as in the classic examples in the additive group $\mathbb{R}$: Baire non-meagre, or measurable non-null), is implied by the compactness-like property (called shift-compactness in [Ost3], cf. [MilO]).
that any null sequence \( z_n \) (i.e. \( z_n \to 1_G \)) has a ‘translator’ \( s \in S \) and sub-sequence \( z_{n(m)} \) with \( \{ s \cdot z_{n(m)} : m \in N \} \subseteq S \); the latter, being a stronger property, can often provide a better heuristic tool. Results of this type go back to Steinhaus [Ste] on the line and Weil [Wei, p. 50] in a locally compact topological group (see e.g. Grosse-Erdmann [GroE]), and to Kemperman [Kem] (cf [Kuc, Lemma 3.7.2], and [BinO1, Th. K] where this is ‘Kemperman’s Theorem’, [BinO5, Th. 1(iv)]). For present purposes it is natural to call shift-compactness a strong Steinhaus-Weil-like property. A first study of the closeness of the two Steinhaus-Weil-like properties appears most recently in [Ost6] by way of the Effros Opening Mapping Principle. Recently, in [BinO7], in work on subadditivity and mid-point convexity, with ‘negligibility’ interpreted via the Christensen Haar-null subsets of a Banach space, we replaced shift-compactness by the already established Steinhaus-Weil property due to Christensen [Chr1,2], or its extension due to Solecki [Sol2]. This new perspective motivates the present return to the question of when the Steinhaus-Weil property implies shift-compactness, and hinges on two themes. The first is the Lebesgue density theorem, which Kemperman [Kem] used to reprove the Steinhaus-Weil theorem, very much a local property. The second was our reliance [BinO7] on a localized version of the Steinhaus-Weil property: in \( S \) the relative open neighbourhoods of all points were to have the Steinhaus-Weil property. Taken together, these suggested the need to characterize in a topological group those analogues of the Lebesgue density topology ([HauP], [GofNN], [GofW]) that imply shift-compactness, a matter we turn to in \( \S 2 \). Here we prove Theorems 1 and 2: we study category analogues of the Lebesgue density topology. We turn in \( \S 3 \) to Hashimoto ideal topologies and in \( \S 4 \) to properties of Steinhaus-Weil type and converses (cf. Prop. 2). We establish in \( \S 5 \) the equivalence of weak and strong Steinhaus-Weil-like properties in the presence of three topological restrictions, taking what we call the Kemperman property in \( \S 2 \) as a weak form of the Steinhaus-Weil property. This is reminiscent of the characterization of Borel measures on \( \mathbb{R} \) having the Steinhaus-Weil property, for which see [Mos] ([Sim] for the Haar case) and the recent [Dan]. We close in \( \S 6 \) with some complements.

We remind the reader of the tension between two of our themes here: density topologies and topological groups. The real line is not a topological group under the (Lebesgue) density topology (see e.g. [Sch, Prop. 1.9], [BinO6, \( \S 4 \)]). Instead, what is relevant here is semi-topological group structure [ArhT], in which it is the shifts (one argument), rather than multiplication (two ar-
The Lebesgue Density Theorem, which underlies the density topology (or topologies) crucial here, is already relevant to (though less well known than) the Lebesgue Differentiation Theorem, on the relationship between differentiation and the Lebesgue integral. The first is usually obtained from the second by specializing to indicator functions $1_A$. Relevant here are Vitali’s covering lemma and weak $L_1$-estimates for the Hardy-Littlewood maximal function; for textbook treatment see e.g. [Rud, Th. 8.8], [SteiS, 3.1.2].

Thus as well as the historical references to Hausdorff in 1914 [Hau] and Denjoy in 1915 [Den], the paper relates to Lebesgue’s approach to the fundamental theorem of calculus. Its roots may thus be traced back to the roots of calculus itself.

## 2 Density topologies

Let $G$ be a separable topological group metrized by a *right*-invariant metric $d = d_R^G$ fixed throughout, allowing the topology to be denoted $\mathcal{T}_d$, or $\mathcal{T}$. (This is possible by the *Birkhoff-Kakutani metrization theorem*, [HewR, II.8, p. 70 Th., p. 83 Notes], [Ost3].) We make free use of

$$||t|| := d_R^G(1_G, t),$$

referred to as the *group norm* of $G$, for which see the textbook account in [ArhT, §3.3] or [BinO4], and denote by $B_\delta(g) := \{h : ||hg^{-1}|| < \delta\} = B_\delta(1_G)g$ the open $\delta$-ball centred at $g$, briefly the open $\delta$-neighbourhood ($\delta$-*nhd*) of $g$; we use $B_\delta$ to denote $B_\delta(1_G)$. For $G$ locally compact, we denote (left) Haar measure by $\eta$, or context permitting by $|\cdot|$, by analogy with the group norm in view of their close relationship. We have in mind, as canonical examples, $\mathbb{R}$ or $\mathbb{R}_+$ under the usual (Euclidean) topology, denoted $\mathcal{E}$. For *any* topology $\tau$ on $G$, we write $\mathcal{F}(\tau), \mathcal{F}_\sigma(\tau), \mathcal{G}_\delta(\tau)$ for the corresponding closed sets etc., $\mathcal{B}(\tau)$ for the *Baire* sets, i.e. the sets with the Baire Property (BP), $\mathcal{B}_0(\tau)$ for the corresponding meagre sets, and $\mathcal{B}_+(\tau)$ for the non-meagre members of $\mathcal{B}(\tau)$. If $(G, \mathcal{T})$ is suppressed, $(\mathbb{R}, \mathcal{E})$ or $(\mathbb{R}_+, \mathcal{E})$ is to be understood. Thus $\mathcal{B}$ denotes the usual Baire sets and $\mathcal{B}_0$ its negligible sets, the $\sigma$-ideal of meagre sets; analogously, $\mathcal{L}$ denotes the Lebesgue (Haar) measurable sets and $\mathcal{L}_0$ its negligible sets, the $\sigma$-ideal of null (measure-zero) sets. We denote by $\mathcal{M}(G)$ the Borel regular $\sigma$-finite measures on $G$, with $\mathcal{P}(G)$ the subfamily of probability measures; here regularity is taken to imply both inner and outer
regularity (i.e. compact inner approximation and open outer approximation); these play a significant role in §4. We say that a property holds at quasi all points of a set if it holds except on a negligible set (in the category or measure sense).

We will refer to the action of $G$ on itself by $t(x) \mapsto tx$ (or $t(x) = t + x$ in the case of $\mathbb{R}$ — we will feel free to move at will between $(\mathbb{R}, +)$ and $(\mathbb{R}^+, \cdot)$ via the exponential isomorphism). Say that a topology $\tau$ on $G$ is (left) shift-invariant if $tV \in \tau$ for all $t \in G$ and all $V \in \tau$; equivalently: each shift $t : \tau \to \tau$ is continuous.

A weak $\tau$-base for $\tau$ is a subfamily $W$ such that for each non-empty $V \in \tau$ there is $W \in W$ with $\emptyset \neq W \subseteq V$. When $W$ above consists of sets analytic under $\mathcal{T}_d$ (for which see below), the topology is called in [Ost1] a generalized Gandy-Harrington topology, by analogy with its classical antecedent (for a textbook treatment of which see [Gao, Ch. 1]); in such a case the topology $\tau$ satisfies the Baire Theorem (see [Oxt, Ch. 9], [Kec, III.26.18,19, p. 203-4], [Ost1, §2.2]). Here we consider a stronger property generalizing the two observations that

(a): modulo $L_0$ each measurable set is an $\mathcal{F}_\sigma$;
(b): modulo $B_0$ each Baire set is a $\mathcal{G}_{\delta}$ ([Oxt, Th. 4.4], cf. [Kec, 8.23])

(these are the forms in which the results are usually stated; it is the similarities, rather than the distinctions, between $\mathcal{F}_\sigma$ and $\mathcal{G}_{\delta}$ that are relevant here).

Say that $\tau$ has the strong Gandy-Harrington property if modulo $B_0(\tau)$ each $B(\tau)$ set is analytic under $\mathcal{T}_d$. (Again see the references above.)

Denote by $D_L$ the family of all sets $M$ all of whose points are density points (i.e. have Lebesgue (Haar) density 1, in the sense of Martin [Mar1,2] or in the more general context Mueller [Mue] — see the more recent development in [Ost3]; cf. [BinO4] for normed groups, [Oxt2] for $\mathbb{R}$). As noted by Haupt and Pauc [HauP] in $\mathbb{R}$, $D_L$ forms a topology, the (Lebesgue) density topology. It is related to Denjoy approximate continuity. It can be generalized to Haar measure. It is a fine topology (refining topology); see [CieLO], [EvaG], [KanK], and [LukMZ], for background on such fine topologies. (For other topologies derived from notions of ‘density point’ see [Wil]; for aspects of translation invariance see [WilK].)

We list below a number of qualitative properties of $D_L$, (i)-(viii), all of them classical. We name property (iv) the Kempermann property: see §1 for the motivation, and (vii) the Nikodym property after [Ost6]. Property (viii) suggests a category analogue $D_B$ of $D_L$; we prove the category analogues of
(i)-(vii) in Theorems 1 and 2 below.

(i) \( \mathcal{D}_L \) is a fine topology (i.e. refining \( \mathcal{T}_d \)) which is shift-invariant:

\[
S \subseteq \mathcal{D}_L \implies \bigcup S \in \mathcal{D}_L, \\
V, V' \in \mathcal{D}_L \implies V \cap V' \in \mathcal{D}_L, \\
\mathcal{T} \subseteq \mathcal{D}_L, \\
tV \in \mathcal{D}_L \quad (t \in G, V \in \mathcal{D}_L);
\]

(ii) the sets in \( \mathcal{D}_L \) are measurable: \( \mathcal{D}_L \subseteq \mathcal{L} \);

(iii) the \( \mathcal{D}_L \)-boundary of a measurable set is null:

\[
M \setminus \text{int}_{\mathcal{D}_L}(M) \in \mathcal{L}_0 \quad (M \in \mathcal{L});
\]

(iv) the Kemperman property, that any open neighbourhood of the identity meets its own small displacements non-meagerly: for \( 1_G \in U \in \mathcal{D}_L \) there is \( \delta > 0 \) with

\[
U \cap (tU) \in \mathcal{B}_+(\mathcal{D}_L) \quad (||t|| < \delta);
\]

(v) \( \mathcal{D}_L \) is a strong generalized Gandy-Harrington topology: modulo \( \mathcal{B}_0(\mathcal{D}_L) \) each \( \mathcal{B}(\mathcal{D}_L) \) set is analytic under \( \mathcal{T}_d \) and in fact \( \mathcal{F}_\sigma(\mathcal{T}_d) \cap \mathcal{D}_L \) is a weak \( \mathcal{D}_L \)-base, so that \( \mathcal{D}_L \) is a Baire space;

(Proof: Any set \( M \in \mathcal{D}_L \) contains a \( \mathcal{T}_d \)-closed set \( F \) of positive measure. Let \( H \) be a \( \mathcal{G}(\mathcal{T}_d)_\delta \)-null set covering the null set of non-density points; then \( F \setminus H \in \mathcal{D}_L \cap \mathcal{F}_\sigma(\mathcal{T}_d) \).

(vi) the \( \mathcal{D}_L \)-Baire sets/meagre sets are identical with respectively, the measurable sets and the null sets:

\[
\mathcal{B}(\mathcal{D}_L) = \mathcal{L}, \quad \mathcal{B}_0(\mathcal{D}_L) = \mathcal{L}_0;
\]

(vii) the Nikodym property of preservation of category under displacements (see [Ost2,6] for background and references):

(a) \( tU \in \mathcal{B}(\mathcal{D}_L) \quad (t \in G, U \in \mathcal{B}(\mathcal{D}_L)) \), and

(b) \( tU \in \mathcal{B}_0(\mathcal{D}_L) \) iff \( U \in \mathcal{B}_0(\mathcal{B}_L) \quad (t \in G) \);

(viii) \( x \) is a density point of a measurable set \( M \) iff \( x \in \text{int}_{\mathcal{D}_L}(M) \).

So \( \mathcal{D}_L \) yields a topological characterization of local behaviour w.r.t. measure. Property (viii) calls for the Haar generalization of the Lebesgue Density Theorem [Oxt, Ch. 3]. Below this will be viewed as a special case of the
Banach Localization Principle (or Banach’s Category Theorem, [Oxt, Ch. 16]; cf. [Ost1]).

We now define a topology $\mathcal{D}_B$ with properties analogous to (i)-(viii) in respect of $B$; here (viii) is a definition of category-density point.

**Definition.** Call $H$ $\tau$-locally comeagre at $x \in H$ if there is a $\tau$-open nhd $U$ of $x$ such that $U \setminus H$ is meagre. In this case each point of $H \cap U$ has this property; note the monotonicity: if $H \subseteq H'$ and $H$ has the property at $x$, then also $H'$ has it at $x$. Say that $H$ is $\tau$-locally comeagre at all of its points if for each $x \in H$ there is a $\tau$-open nhd $U$ of $x$ such that $U \setminus H$ is meagre. Alternatively, note that $H$ is open under the refinement topology generated by the family \( \{ U \setminus L : U \in \tau, L \in \mathcal{B}_0(\tau) \} \). We consider ‘ideal topology’ refinements such as this, generated by a general $\sigma$-ideal in place of $\mathcal{B}_0(\tau)$, in the next section.

**Theorem 1.** For $\mathcal{T} = T_\delta$ let $\mathcal{D}_B(\mathcal{T})$ be the family of sets which are $\mathcal{T}$-locally co-meagre at all of their points. Then:

(i) $\mathcal{D}_B(\mathcal{T})$ is a shift-invariant topology on $G$ refining $\mathcal{T}$, so that

$$t\mathcal{D}_B(\mathcal{T}) \subseteq \mathcal{D}_B(\mathcal{T}) \quad (t \in G) \text{ and } \mathcal{T} \subseteq \mathcal{D}_B(\mathcal{T});$$

(ii) the sets in $\mathcal{D}_B(\mathcal{T})$ are $\mathcal{T}$-Baire:

$$\mathcal{D}_B(\mathcal{T}) \subseteq \mathcal{B}(\mathcal{T});$$

(iii) the boundary points of any $\mathcal{T}$-Baire set $H$ form a $\mathcal{T}$-meagre set:

$$H \setminus \text{int}_{\mathcal{D}_B}(H) \in \mathcal{B}_0(\mathcal{T}) \text{ for } H \in \mathcal{B}(\mathcal{T});$$

in fact, if $S$ is Baire, then $S$ has a non-empty $\mathcal{D}_B(\mathcal{T})$-interior in each nhd on which it is dense and non-meagre.

(iv) Kemperman property: for $0 \in U \in \mathcal{D}_B(\mathcal{T})$ there is $\delta > 0$ with

$$U \cap (tU) \in \mathcal{B}_+(\mathcal{D}_B(\mathcal{T})) \quad (||t|| < \delta);$$

(v) $\mathcal{D}_B$ is a strong generalized Gandy-Harrington topology: modulo $\mathcal{B}_0(\mathcal{D}_L(\mathcal{T}))$ each $\mathcal{B}(\mathcal{D}_L(\mathcal{T}))$ set is analytic under $\mathcal{T}$, and in fact $\mathcal{D}_B(\mathcal{T}) \cap \mathcal{G}_0(\mathcal{T})$ is a weak $\mathcal{D}_B(\mathcal{T})$-base, so $(G, \mathcal{D}_B(\mathcal{T}))$ is a Baire space.

**Proof.** (i) Evidently $G$ and $\emptyset$ are in $\mathcal{D}_B(\mathcal{T})$. For an arbitrary $\mathcal{H} \subseteq \mathcal{D}_B(\mathcal{T})$, the union $H := \bigcup \mathcal{H}$ is $\mathcal{T}$-locally co-meagre at each element of $H$, by monotonicity. Next, suppose $x \in H \cap H'$, with $H, H' \in \mathcal{D}_B(\mathcal{T})$. Choose $V, V'$ open
nhds of \( x \) meeting \( H, H' \) in comeagre sets. Then \( x \in W = V \cap V' \) is an open nhd of \( x \). As \( H \cap W \) and \( H' \cap W \) are co-meagre on \( W \), by Baire’s Theorem, so is their intersection on \( W \); so \( H \cap H' \) is \( T \)-locally co-meagre at \( x \).

(ii) Suppose \( H \) is \( T \)-locally comeagre at all \( x \in H \). Being metrizable and separable, \( G \) is hereditarily Lindelöf [Dug, VIII §6 and Th. 7.3], so \( H \) is Baire; indeed, if \( \{U_n\} \) is a countable open cover of \( H \), with each \( U_n \setminus H \) meagre, then \( H = \bigcup_n (U_n \cap H) = \bigcup_n U_n \setminus (U_n \setminus H) \), which is Baire, since each set \( U_n \setminus (U_n \setminus H) \) is Baire.

(iii) If \( S \) is non-meagre, it is dense in some open nhd \( I \). Then \( T := I \setminus S \) is meagre: for otherwise, \( T \) is (Baire and) non-meagre. Then \( T \) is dense on some (non-empty) open \( J \subseteq I \). Being Baire, both \( S \) and \( T \) are, modulo meagre sets, \( G_\delta(T) \)-sets dense on \( J \). So they meet, by Baire’s Theorem – a contradiction.

Let \( I \) be a maximal family of nhds \( I \) on which \( S \) is co-meagre. Then \( \bigcup \{I \cap S : I \in I\} \) is \( T \)-open. Put \( S' = S \setminus \bigcup \{I \cap S : I \in I\} \). Then \( S' \) is meagre; otherwise, as before \( S' \) is dense in some nhd \( I \) and co-meagre on \( I \), contradicting maximality of \( I \).

(iv) If \( 1_G \in H \in D_B(T) \), and \( H = U \setminus N \), choose \( \delta > 0 \) such that \( B_\delta(1_G) \subseteq U \). Then \( \emptyset \neq B_\delta(1_G) \cap tB_\delta(1_G) \), for \( ||t|| < \delta \), so

\[
H \cap (tH) \supseteq B_\delta(1_G) \cap tB_\delta(1_G) \setminus (N \cup tN) \in B_+(D_B(T)).
\]

(v) If \( H \in D_B(T) \), and \( H = U \setminus N \) with \( U \in T \) and \( N \) meagre (in the sense of \( T \)) we may chose a larger meagre \( F_\delta(T) \)-set \( M \supseteq N \), and then \( H' = U \setminus M \in G_\delta(T) \cap D_B(T) \). □

Recall the observation of Haupt and Pauc [HauP] that (writing \text{nwd} for nowhere dense)

\[
M \text{ is meagre in } D_\mathcal{E} \text{ iff } M \text{ is nwd in } D_\mathcal{E} \text{ iff } M \text{ is null} \quad (H-P)
\]

[Kec, 17.47]. This shows very clearly how changing from the original topology \( T \) (\( \mathcal{E} \) in the Euclidean case) to the density topology \( D \) changes from the measure case to the Baire (or topological) case. This is the basis for the use of bitopology in [BinO2].

Theorem 2 below extends the list (i)-(v) in Theorem 1 to (vi), (vii) (as noted above (viii) becomes a matter of definition).

**Theorem 2.** For \( T = T_0 \) a set \( D \) is \( \mathcal{D}_B(T) \)-\text{nwd} iff \( D \) is meagre in \( T \), and so likewise for \( \mathcal{D}_B(T) \)-\text{meagre} sets \( D \). So:
(vi) $B_0(D_B(T)) = B_0(T)$ and $B(D_B(T)) = B(T)$.

(vii) Nikodym property:
(a) $tU \in B(D_B(T))$ for $U \in B(D_B(T))$, and
(b) $tU \in B_0(D_B(T))$ iff $U \in B_0(B_B(T))$.

Proof. If $D$ is meagre, then its complement is co-meagre, and so $D$ avoids any $D_B(T)$-open set. For the converse, take a maximal family $W$ of $T$-sets $W$ with $D \cap W$ meagre. Then $\bigcup\{D \cap W : W \in W\}$ is meagre by Banach’s Category Theorem. Put $D' = D \setminus \bigcup\{D \cap W : W \in W\}$. Suppose that $D'$ is non-meagre. Then for some open nhd $U$ the set $D'$ is non-meagre on every open subset of $U$; but $D'$ is $D_B(T)$-nwd, so there is an open nhd $V$ and meagre $M_V$ with $V \setminus M_V$ disjoint from $D'$. Then $D' \cap V \subseteq M_V$, a contradiction. So $D'$ is indeed meagre, and so is $D$.

If $D$ is a countable union of $D_B(T)$-nwd sets, then it is meagre in $T$.

The remaining assertions are now clear. □

3 Hashimoto ideal topologies

As in $(H-P)$ above, a key role is played by the family of meagre sets (in $E$, or $B_L$) and (Lebesgue-) null sets. Each forms a $\sigma$-ideal of small sets and gives rise to a Hashimoto topology (= ‘ideal topology’ according to [LukMZ, 1.C]), to which we now turn.

Definition. For $\mathcal{I}$ a $\sigma$-ideal of subsets of $X$ and $\tau$ a topology on $X$, say that a set $S$ is $\mathcal{I}$-nearly $\tau$-open if for some $\tau$-open set $U$ and elements $M, N$ in $\mathcal{I}$

$$S = (U \setminus N) \cup M.$$  

When relevant, we will include the axioms of set theory we use in parentheses after the theorem number. As usual, we write ZF for Zermelo-Fraenkel and DC for Dependent Choice.

The following result is an embellishment of Hashimoto’s early insight [Has]; there is a readable account by Janković and Hamlett in [JanH].

Theorem 3 (ZF+DC; cf. [Has], [JanH]). For a topology $\tau$ with countable basis $B$ and a $\sigma$-ideal $\mathcal{I}$, the (Hashimoto) topology generated by the sets

$$\mathcal{H} := \{V \setminus M : V \in \tau, M \in \mathcal{I}\}$$
is $\mathcal{H}$ itself, so that, in particular, each $W \in \mathcal{H}$ is $\mathcal{I}$-nearly $\tau$-open and has the representation

$$W = \left( \bigcup_{B \in \mathcal{B}_W} B \right) \setminus M,$$

for some $M \in \mathcal{I}$, where

$$\mathcal{B}_W := \{ B \in \mathcal{B} : B \setminus L \subseteq W \text{ for some } L \in \mathcal{I} \}.$$  

Furthermore, if no non-empty $\tau$-open set is in $\mathcal{I}$, then:

(i) a set is $\mathcal{H}$-nowhere dense iff it is the union $N \cup M$ of a $\tau$-nowhere dense set and an $\mathcal{I}$ set;

(ii) the $\mathcal{H}$-Baire sets are the $\mathcal{I}$-nearly $\tau$-Baire sets;

(iii) for $\mathcal{I}$ the meagre sets of $\tau$, if $\tau$ is a Baire topology, then so is $\mathcal{H}$.

**Proof.** For a fixed non-empty set $W$ that is a union of sets in $\mathcal{H}$, put

$$\mathcal{B}_W := \{ B \in \mathcal{B} : B \setminus L \subseteq W \text{ for some } L \in \mathcal{I} \}.$$  

As this is countable, by DC (see [Wag, Ch. 13]) there is a selector $L(.)$ defined on $\mathcal{B}_W$ such that $L(B) \in \mathcal{I}$ for each $B \in \mathcal{B}_W$; then $B \setminus L(B) \subseteq W$. Set $M(B) := B \cap L(B) \setminus W$, so that $B \setminus M(B) = B \setminus L(B) \cup (B \cap L(B) \cap W) \subseteq W$. Then $M(B) \cap W = \emptyset$. So putting

$$M := \bigcup_{B \in \mathcal{B}_W} M(B),$$

$M \cap W = \emptyset$. Also $M \in \mathcal{I}$ as $M(B) \subseteq L(B) \in \mathcal{I}$. Then, as $B \setminus M(B) \subseteq W$ for each $B \in \mathcal{B}_W$,

$$\left( \bigcup_{B \in \mathcal{B}_W} B \right) \setminus M \subseteq W.$$  

In fact, equality holds: indeed, if $x \in W$, then $x \in B \setminus L$ for some $B \in \mathcal{B}_W$ and $L \in \mathcal{I}$ (and $B \setminus L \subseteq W$). Then $x \notin M$ as $x \in W$, and so $x \in B \setminus M$.

So in particular $W$ is $\mathcal{I}$-nearly $\tau$-open.

(i) This follows since the $\mathcal{I}$-nearly $\tau$-open sets are a $\sigma$-ideal containing $\mathcal{H}$.

(ii) If $N$ is $\mathcal{H}$-nowhere dense, then so is its $\mathcal{H}$-closure $\bar{N}$. So $W := X \setminus \bar{N}$ is $\mathcal{H}$-open and $\mathcal{H}$-everywhere dense. Write $W = (V \setminus M)$ with $V \in \tau$ and $M \in \mathcal{I}$. It is enough to show now that $V$ is $\tau$-everywhere dense. Indeed, for $\tau$-open $U$, as $U$ is also $\mathcal{H}$-open, $U \cap (V \setminus M) = (U \cap V) \setminus M$ is non-empty, as otherwise $U \cap V \subseteq M$, a contradiction.

Conversely, if $V$ is $\tau$-everywhere dense and $M \in \mathcal{I}$, then we are to show that $(X \setminus V) \cup M$ is $\mathcal{H}$-nowhere dense. For non-empty $\tau$-open $U$ and $M' \in \mathcal{I}$,
the set \((U \setminus M') \cap (V \setminus M) = (U \cap V) \setminus (M \cup M')\) is non-empty (otherwise \(M \cup M'\) covers the non-empty set \(U \cap V\)). So \(V \setminus M\) is \(\mathcal{H}\)-everywhere dense, and so \(X \setminus (V \setminus M)\) is \(\mathcal{H}\)-nowhere dense and \(X \setminus (V \setminus M) = (X \setminus V) \cup M\).

(iii) Straightforward, since if \(W_n\) for \(n \in \mathbb{N}\) is \(\mathcal{H}\)-everywhere dense, then \(X \setminus W_n\) is \(\mathcal{H}\)-nowhere dense, and so

\[
X \setminus W_n = X \setminus G_n \cup M_n
\]

for some \(G_n\) \(\tau\)-open \(\tau\)-everywhere dense, and \(M_n \in \mathcal{I}\). That is: the topology is Baire. \(\square\)

Cautionary example. For \(\mathcal{I} = \mathcal{L}_0\), the Lebesgue null sets, decompose \(\mathbb{R}\) into a meagre and a null set [Oxt, Th. 1.6] to see that starting with \(\tau\) the usual topology of \(\mathbb{R}\) yields a Hashimoto topology that is not Baire, by (i) above.

4 Steinhaus-Weil-like properties

The Kemperman property (iv) of Theorem 1 above, for the \(\mathcal{D}\)-open sets \(U\):

\[
U \cap (tU) \in \mathcal{B}_+(\mathcal{D}) \quad (||t|| < \delta),
\]

yields the Steinhaus-Weil property \(B_\delta \subseteq A^{-1}A\) for a set \(A\) (see e.g. [BinO5], [BinGT, 1.1.2], [BinO8]), provided the Kemperman property extends to \(A\), since

\[
ta = a' \iff t = a'a^{-1} \in AA^{-1}.
\]

So we regard the Kemperman property as a weak Steinhaus-Weil-like property. The extension beyond \(\mathcal{D}\)-sets to \(\mathcal{B}_+(\mathcal{D})\) will indeed hold in the presence of the Nikodym property (§2 above), when \(U \setminus A \in \mathcal{B}_0(\mathcal{D})\) for some \(U \in \mathcal{D}\), as then \(t(U \setminus A) \in \mathcal{B}_0(\mathcal{D})\). The fact that this is so for \(A\) a Haar-measurable set, or a Baire set, is the source of the most direct proofs, recalled below for completeness, of the Steinhaus-Pettis Theorem (see e.g. [BinO4, Th. 6.5]). These generalize (from the Euclidean case) a Lemma first observed by Kemperman ([Kem]; cf. [Kuc, Lemma 3.7.2]).

In Lemma 2 below we take a more direct approach – a streamlined version of the ‘uniformity’ approach in [Hal, Th. 61.A] – inspired by Stromberg [Str], but with translational subcontinuity of measure \(\mu \in \mathcal{M}(G)\) (its definition below motivated by the upper semicontinuity of the map \(x \mapsto \mu(xK)\)), in
lieu of *translation-invariance* of measure, and referring to the group norm, more thematic here. This is followed by its Baire-category analogue. Below, for \( \eta \) a left Haar measure of a locally compact group \( G \), \( \mathcal{M}^+(\eta) \) denotes the left Haar measurable sets of positive (finite) measure, by analogy with the notation \( \mathcal{B}^+ = \mathcal{B}^+ (\mathcal{T}) \) for the non-meagre Baire sets.

A key tool is provided by a form of the ‘telescope’ or ‘tube’ lemma (cf. [Mun, Lemma 5.8]). Our usage of upper semicontinuity in relation to set-valued maps follows [Rog], cf. [Bor].

**Lemma 1.** (cf. [BeeV]). For compact \( K \subseteq G \), the map \( t \mapsto tK \) is upper semicontinuous; in particular, for \( \mu \in \mathcal{M}(G) \),

\[ m_K : t \mapsto \mu(tK) \]

is upper semicontinuous, hence \( \mu \)-measurable. In particular, if \( m_K(t) = 0 \), then \( m \) is continuous at \( t \).

**Proof.** For \( K \) compact and \( V \supseteq K \) open, pick for each \( k \in K \), an \( r(k) > 0 \) with \( kB_{2r(k)} \subseteq V \). By compactness, there are \( k_1, \ldots, k_n \) with \( K \subseteq \bigcup_j B_{r(k_j)} k_j \subseteq V \); then for \( \delta := \min_j r(k_j) > 0 \)

\[ tK \subseteq \bigcup_j tB_{r(k_j)} k_j \subseteq \bigcup_j B_{2r(k_j)} k_j \subseteq V \quad (||t|| < \delta). \]

To prove upper semicontinuity of \( m_K \), fix \( t \in G \). For \( \varepsilon > 0 \), as \( tK \) is compact, choose by outer regularity an open \( U \supseteq tK \) with \( \mu(U) < \mu(tK) + \varepsilon \); by the first assertion, there is an open ball \( B_\delta \) at \( 1_G \) with \( B_\delta tK \subseteq U \), and then \( \mu(B_\delta(t)K) \leq \mu(U) < \mu(K) + \varepsilon \). \( \square \)

Of course, in a locally compact group \( G \) and with \( \mu \) a Haar measure, \( m_K \) is constant. By Luzin’s theorem, the restriction of \( m_K \) to appropriate non-null subsets is (relatively) continuous; but of greater significance, as emerges in [BinO8], is a form of subcontinuity *relativized to a fixed sequence* \( t_n \to 1_G \), linking the concept to Solecki’s amenability at \( 1 \) [Sol2] (see §8.5), and the latter, like *outright continuity* at \( 1_G \), yields the Steinhaus-Weil property. Regularity of measure also plays a part; it is likewise key in establishing in [Kom] the connection between the (wider) Steinhaus-Weil property concerning \( AB^{-1} \) and *metric transitivity* of measure (the co-negligibility/ ‘residuality’ of \( AD \) for dense \( D \) cf. [Kuc, Th. 3.6.1], [CichKW, Ch. 7]), and the related *Smítal property* (cf. [BarFN]). We begin with a
Cautionary example. In any separable group $G$, for $D := \{d(n) : n \in \mathbb{N}\}$ a dense subset, define a regular probability measure by $\mu_D := \sum_{n \in \mathbb{N}} 2^{-n} \delta_{d(n)}$, with $\delta_g$ the degenerate measure at the point $g$ (point-mass at $g$); then $\mu_D(U) > 0$ for all non-empty $U$, as $\mu_D(d(n)) = 2^{-n}$. However, there exist arbitrarily small translations $t$ with $\mu_D(tD) = 0$ (since $D$ is meagre – cf. [MilO]). This is particularly obvious in the case $G = \mathbb{R}$ with $D = \mathbb{Q}$, on taking small irrational translations; whilst the situation here is attributable to $\mu_D$ having atoms (not just being singular w.r.t. Lebesgue measure – see the Mospan property below), its obverse occurs when $\mu(U) = 0$ for some non-atomic $\mu \in \mathcal{P}(G)$ and $U$ non-empty open, as there is a translation $t = d(n)$ such that $\mu(tU) > 0$ (as $\{d(n)U : n \in \mathbb{N}\}$ covers $G$). Then $\mu(U) > 0$ for $\mu(\cdot) = \mu(t\cdot)$, which is non-atomic.

Motivated by this last comment, and with Proposition 3 below in mind, let us note a non-atomic modification $\tilde{\mu}$ of $\mu_D$ making all open sets $\mu$-non-null. In $\mathcal{P}(G)$, under its (separable, metrizable) weak topology, the non-atomic measures form a dense $G_\delta$ (see e.g. [Par, II.8]). So for a non-atomic $\tilde{\mu}$ take $\mu := \sum_{n \in \mathbb{N}} 2^{-n} d(n) \tilde{\mu}$, which is non-atomic with $\mu(U) > 0$ for non-empty open $U$.

It is inevitable that measure significance of small changes relates to amenability (see the Reiter condition in [Pat, Prop. 0.4], cf. §6.5).

Definition. For $\mu \in \mathcal{P}(G)$ and compact $K \subseteq G$, noting that $\mu_\delta(K) := \inf\{\mu(tK) : t \in B_\delta\}$ is weakly decreasing in $\delta$, put

$$\mu_-(K) := \sup_{\delta > 0} \inf\{\mu(tK) : t \in B_\delta\}.$$  

Then, by Lemma 1,

$$0 \leq \mu_-(K) \leq \mu(K).$$

We will say that the measure $\mu$ is translation-continuous, or just continuous, if $\mu(K) = \mu_-(K)$ for all compact $K$; evidently $m_K(.)$ is continuous if $\mu$ is translation continuous, since $m_K(st) = m_{tK}(s)$ and $tK$ is compact whenever $K$ is compact. For $G$ locally compact this occurs for $\mu$ the left-Haar measure $\eta$, and also for $\mu$ absolutely continuous w.r.t. to $\eta$ (see below). We call $\mu$ maximally discontinuous for $K$ if $0 = \mu_-(K) < \mu(K)$. That a measure $\mu$ singular w.r.t. Haar measure is just such an example was first discovered by Simmons [Sim] (and independently, much later, by Mospan [Mos]). The intermediate situation when $\mu(K) \geq \mu_-(K) > 0$ for all $\mu$-non-null compact $K$ is of significance; then we call $\mu$ subcontinuous. The notion of subcontinuity
for functions goes back to [Ful] (cf. [Bou]): as applied to the function $m_{sK}(t)$, regarded as a map into the positive reals $(0, \infty)$, subcontinuity at $t = 1_G$ requires that for every sequence $t_n \to 1_G$ there is a subsequence $t_{m(n)}$ with $m_{sK}(t_{m(n)})$ convergent (to a positive value). Thus our usage, applied to a measure $\mu$, is equivalent to demanding, for each $\mu$-non-null compact $K$ and any null sequence $\{t_n\}$ (i.e. with $t_n \to 1_G$), that there be a subsequence $\mu(t_{m(n)} K)$ bounded away from 0. This already is reminiscent of amenability at $1_G$ – again see §6.5. In Lemma 2 below (H-K) is for ‘Haar-Kemperman’, as in Proposition 1 below.

**Lemma 2.** Let $\mu \in \mathcal{P}(G)$. For $\mu$-non-null compact $K \subseteq G$, if $\mu_-(K) > 0$ (i.e. $\mu$ is subcontinuous at $K$), then there is $\delta > 0$ with

$$t K \cap K \in \mathcal{M}_+(\mu) \quad (||t|| < \delta), \quad (H-K)$$

so in particular,

$$B_\delta \subseteq KK^{-1},$$

or, equivalently, for $0 < ||t|| < \delta$

$$t K \cap K \neq \emptyset \quad (||t|| < \delta).$$

**Proof.** By continuity at $1_G$ of the map $m_K$, choose $\delta > 0$ so that $\mu(B_\delta, K) > \mu(K)/2$, for $B_\delta$ the open ball $B_\delta$ centred at $1_G$.

Choose $\Delta > 0$ with $\mu(\Delta(K)) > \mu_-(K)/2$. By outer regularity of $\mu$, choose $U$ open with $K \subseteq U$ and $\mu(U) < \mu(K) + \mu_-(K)/2$. By upper semicontinuity of $t \mapsto tK$, w.l.o.g. $B_\delta K \subseteq U$ for some $\delta < \Delta$. Then (H-K) holds: otherwise, for $t \in B_\delta$, as $\mu(tK \cap K) = 0$,

$$\mu_\delta(K) + \mu(K) \leq \mu(tK) + \mu(K) = \mu(tK \cup K) \leq \mu(U) < \mu(K) + \mu_-(K)/2,$$

so $\mu_-(K)/2 < \mu(\Delta(K)) < \mu_\delta(K) < \mu_-(K)/2$, a contradiction. Given $||t|| < \delta$ and $tK \cap K \in \mathcal{M}_+$, take $s \in tK \cap K \neq \emptyset$; then $s = ta$ for some $a \in K$, so $t = sa^{-1} \in KK^{-1}$. Conversely, $t \in B_\delta \subseteq KK^{-1}$ yields $t = a'a^{-1}$ for some $a, a' \in K$; then $a' = ta \in K \cap tK$. □

Proposition 1M/1B below, which occurs in two parts (measure and Baire category cases), unifies and extends various previous results due to among others Steinhaus, Weil, Kemperman, Kuczma, Stromberg, Weil, Wilczyński, Simmons [Sim] and Mospán [Mos] – see [BinO5,8] for references.
Proposition 1M (Haar-Kemperman property). Let $\mu \in \mathcal{P}(G)$ with each map $m_K : t \mapsto \mu(tK)$, for non-null compact $K \subseteq G$, continuous at $1_G$. Then for $\mu$-measurable $A$ with $0 < \mu(A) < \infty$ there is $\delta > 0$ with

$$tA \cap A \in \mathcal{M}_+(\mu) \quad (||t|| < \delta),$$

so in particular,

$$B_\delta \subseteq AA^{-1},$$

or, equivalently, for $0 < ||t|| < \delta$

$$tA \cap A \neq \emptyset \quad (||t|| < \delta).$$

Proof. By inner regularity of $\mu$, there exists a compact $K \subseteq A$ with $0 < \mu(K) \leq \mu(A) < \infty$. Now apply the previous lemma. □

We can now give a sharpened form of a result of Mospan.

Corollary 1 (Mospan property, [Mos, Th. 2]). If $1_G \notin \text{int}(KK^{-1})$, then $\mu_-(K) = 0$, i.e. $\mu$ is maximally discontinuous; equivalently, there is a ‘null sequence’ $t_n \to 1_G$ with $\lim_n \mu(t_nK) = 0$.

Conversely, if $\mu(K) > \mu_-(K) = 0$, then there is a null sequence $t_n \to 1_G$ with $\lim_n \mu(t_nK) = 0$, and there is $C \subseteq K$ with $\mu(K \setminus C) = 0$ with $1_G \notin \text{int}(CC^{-1})$.

Proof. The first assertion follows from Lemma 2. For the converse, as in [Mos]: suppose that $\mu(t_nK) = 0$, for some sequence $t_n \to 1_G$. By passing to a subsequence, we may assume that $\mu(t_nK) < 2^{-n-1}$. Put $D_m := K \setminus \bigcap_{n \geq m} t_nK \subseteq K$; then $\mu(K \setminus D_m) \leq \sum_{n \geq m} \mu(t_nK) < 2^{-m}$, so $\mu(D_m) > 0$ provided $2^{-m} < \mu(K)$. Now choose compact $C_m \subseteq D_m$, with $\mu(D_m \setminus C_m) < 2^{-m}$. So $\mu(K \setminus C_m) < 2^{1-m}$. Also $C_m \cap t_nC_m = \emptyset$, for each $n \geq m$, as $C_m \subseteq K$; but $t_n \to 1_G$, so the compact set $C_mC_m^{-1}$ contains no interior points. Hence, by Baire’s theorem, neither does $CC^{-1}$ for $C = \bigcup_m C_m$ which differs from $K$ by a null set. □

The significance of Corollary 1 is that in alternative language it asserts a Converse Steinhaus-Weil Theorem.

Proposition 2. A regular Borel measure $\mu$ on a topological group $G$ has the Steinhaus-Weil property iff
(i) for each non-null compact set $K$, the map $m_K : t \to \mu(tK)$ is subcontinuous at $1_G$;
(ii) for each non-null compact set $K$ there is no ‘null’ sequence $t_n \to 1_G$ with $\mu(t_nK) \to 0$.

**Remark.** In the locally compact case, Simmons and Mospan both prove that this is equivalent to $\mu$ being absolutely continuous w.r.t. Haar measure $\eta$.

If $m_K$ is continuous at $1_G$ for all $K$ then, as $m_K(st) = m_tK(s)$, the map $m_K$ is continuous at all $t$.

For the Baire-category version, which goes back to Piccard and Pettis (see [BinO5] for references), we recall that the quasi-interior, here conveniently denoted $\tilde{A}$ (or $A^q$) of a set $A$ with the Baire property is the largest (usual) open set $U$ such that $U \setminus A$ is meagre; it is a regularly-open set (see [Dug, Ch. 3 Problems, Section 4 Q22], §6.3). We note that $(aA)^q = aA^q$. We learn from Theorem 4 below that the counterpart of this ‘quasi-interior’ for measurable sets is provided by the open sets of the density topology.

**Proposition 1B (Baire-Kemperman property)** ([BinO4, Th. 5.5B/M], [BinO3, §5, Th. K]). *In a normed topological group $G$, Baire under its norm topology, if $A$ is Baire non-meagre, then there is $\delta > 0$ with*

$$tA \cap A \in B_+ \quad (||t|| < \delta);$$

*so in particular,*

$$B_\delta \subseteq AA^{-1}.$$  

**Proof.** If $a \in A^q$, the quasi-interior of $A$, then $1_G \in a^{-1}\tilde{A}$, which is open. So w.l.o.g. we may take $a = 1_G$. Choose $\delta > 0$ so that $B := B_\delta \subseteq \tilde{A}$. Then for $t \in B$, since $t \in B_\delta(t) = tB,$

$$t\tilde{A} \supseteq tB \cap B \neq \emptyset,$$

so being open, $tB \cap B$ is non-meagre (as $G$ is Baire). But, modulo meagre sets $A$ and $\tilde{A}$ are identical. For the remaining assertion, argue as in the measure case. □

Propositions 1M and 1B are both included in Theorem 4 below in the topology refinement context with $B_+ (D_L) = M_+$, and $B_+ (D_B) = B_+ (T_d)$; we
apply the result in Theorem 5. (Recall the discussion in §2 of their properties, enlisted below.)

**Theorem 4 (Displacements Theorem).** In a topological group under the topology of $d^G_R$, let $\mathcal{D}$ be a topology refining $d^G_R$ and having the following properties:

(i) $\mathcal{D}$ is shift-invariant: $x\mathcal{D} = \mathcal{D}$ for all $x$;

(ii) $\mathcal{B}_0(\mathcal{D})$ is left invariant for all $x$;

(iii) ‘Localization property’: $H \setminus \text{int}_\mathcal{D}(H) \in \mathcal{B}_0(\mathcal{D})$ for $H \in \mathcal{B}(\mathcal{D})$;

(iv) the (left) ‘Kemperman property’: for $1_G \in U \in \mathcal{D}$ there is $\delta = \delta_U > 0$ with

$$tU \cap U \in \mathcal{B}_+(\mathcal{D}) \quad (||t|| < \delta);$$

(v) $\mathcal{D}$ is a strong generalized Gandy-Harrington topology: modulo $\mathcal{B}_0(\mathcal{D})$ each $\mathcal{B}(\mathcal{D})$ set is analytic under $d^G_R$, so that $\mathcal{D}$ is a Baire space.

Then for $A \in \mathcal{B}_+(\mathcal{D})$ and quasi all $a \in A$, there is $\varepsilon = \varepsilon_A(a) > 0$ with

$$axa^{-1}A \cap A \in \mathcal{B}_+(\mathcal{D}) \quad (||x|| < \varepsilon);$$

so in particular, with $\gamma_a(x) := axa^{-1}$,

$$\gamma_a(B_x) \subseteq AA^{-1} \quad \text{off a } \mathcal{B}_0(\mathcal{D})\text{-set of } a \in A.$$

**Proof.** For some $U \in \mathcal{D}$ and $N, A' \in \mathcal{B}_0(\mathcal{D})$, $A \setminus A' = U \setminus N$: by (i) and (ii), $U_a = a^{-1}U \in \mathcal{D}$ and $N_a = a^{-1}N \in \mathcal{B}_0(\mathcal{D})$, so $a^{-1}A \supseteq U_a \setminus N_a$ for $a \in A \setminus A'$.

By the Kemperman property, for $a \in A \setminus A'$ there is $\varepsilon = \varepsilon_A(a) > 0$ with

$$xU_a \cap U_a \in \mathcal{B}_+(\mathcal{D}) \quad (||x|| < \varepsilon).$$

Fix $a \in A \setminus A'$. Working modulo $\mathcal{B}_0(\mathcal{D})$-sets which are left invariant (by the Nikodym property), $xa^{-1}A \supseteq xU_a$ and

$$a^{-1}A \cap xa^{-1}A \supseteq U_a \cap (xU_a), \quad (||x|| < \varepsilon).$$

So, since also $axa^{-1}A \in \mathcal{B}(\mathcal{D})$, again by the Nikodym property

$$axa^{-1}A \cap A \in \mathcal{B}_+(\mathcal{D}) \quad (||x|| < \varepsilon).$$

For the remaining assertion, argue as in Prop. 1M above. □
Remark. The map $\gamma_a : x \mapsto axa^{-1}$ in the preceding theorem is a homeomorphism under the topology of the topological group $d^G_H$ (being continuous, with continuous inverse $\gamma_{a^{-1}}$), so $\gamma_a(B_{\varepsilon, A(a)})$ is open, and also open under the finer topology $D$.

Theorem 4 above identifies additional topological properties enabling the Kemperman property to imply the Steinhaus-Weil property. So we regard it as a weak Steinhaus-Weil property; the extent to which it is weaker is clarified by Proposition 2 below. For this we need a $\sigma$-algebra. Recall that $E \subseteq G$ is universally measurable ($E \in \mathcal{U}(G)$) if $E$ is measurable with respect to every measure $\mu \in \mathcal{P}(G)$ – for background, see e.g. [Kec, §21D], cf. [Fre, 434D, 432]; these form a $\sigma$-algebra. Examples are analytic subsets (see e.g. [Rog, Part 1 §2.9], or [Kec, Th. 21.10], [Fre, 434Dc]) and the $\sigma$-algebra that they generate. Beyond these are the provably $\Delta_2^1$ sets of [FenN].

Proposition 2 (cf. BinO8, Cor. 2]). For $\mathcal{H}$ a left invariant $\sigma$-ideal in $G$, put

$$\mathcal{U}_+(\mathcal{H}) = \mathcal{U}(G) \setminus \mathcal{H}.$$ 

If $\mathcal{U}_+(\mathcal{H})$ has the Steinhaus-Weil property, then $\mathcal{U}_+(\mathcal{H})$ has the Kemperman property.

Proof. Suppose otherwise. Then, for some $E \in \mathcal{U}_+(\mathcal{H})$ and some $t_n \to 1_G$, each of the sets $E \cap t_n E$ is in $\mathcal{H}$, and so

$$E_0 := E \setminus \bigcup_n t_n E = E \setminus \bigcup_n (E \cap t_n E) \in \mathcal{U}(G),$$

which is in $\mathcal{U}_+(\mathcal{H})$ (as otherwise $E = E_0 \cup \bigcup [E \cap t_n E] \in \mathcal{H}$). So $1_G \in \text{int}(E_0 E_0^{-1})$. So, for ultimately all $n$, $t_n \in E_0 E_0^{-1}$, and then $E_0 \cap t_n E_0 \neq \emptyset$. But, as $E_0 \subseteq E$, $E_0 \cap t_n E_0 \subseteq E_0 \cap t_n E = \emptyset$, a contradiction. □

Of interest above is the case $\mathcal{H}$ of left-Haar-null sets [Sol2] of a Polish group $G$ (cf. §6.5,6). We close with a result on the density topology $\mathcal{D}_\mu$ generated in a Polish group $G$ from a measure $\mu$; this is an immediate corollary of [Mar]. Unlike the Hashimoto ideal topologies, which need not be Baire topologies, these are Baire. The question of which sets have the Steinhaus-Weil property under $\mu$, hinges on the choice of $\mu$ (see the earlier cautionary example of this section), and indeed on further delicate subcontinuity considerations, related to [Sol2], for which see [BinO8]. In this connection see [Oxt1] and [DieS, Ch. 10].
Proposition 3. For $G$ a Polish group with metric topology $\mathcal{T}_d$, $\mathcal{B}$ a countable basis, and $\mu \in \mathcal{P}(G)$ with $\mu(U) > 0$ for all non-empty $U$, then with density at $g \in G$ computed by reference to $\mathcal{B}_g := \{B \in \mathcal{B} : g \in B\}$, the Lebesgue density theorem holds for $\mu$ and so the generates a density topology $\mathcal{D}_\mu$, refining $\mathcal{T}_d$, which is a Baire topology.

Proof. As $\mathcal{B}$ comprises open sets, the Vitali covering lemma applies (see [Bru, §6.3-4]), and implies that the measure $\mu$ obeys a density theorem (cf. [Kuc, Th. 3.5.1]). So by results of Martin [Mar, Cor. 4.4], the family $\mathcal{D}_\mu$ of sets all of whose points have (outer) density 1 are $\mu$-measurable, and form a topology on $G$ [Mar, Th. 4.1]. It is a Baire topology, by [Mar, Cor. 4.13]. It refines $\mathcal{T}_d$: the points of any open set have density 1, because the differentiation basis consists of open sets, and these all are $\mu$-non-null. □

5 A Shift Theorem

Theorem 5 below establishes a compactness-like property of a density topology $\mathcal{D}$ which, according to the Corollary below, implies the Steinhaus-Weil property for sets in $A \in \mathcal{B}_+(\mathcal{D})$. So we may regard it as a strong Steinhaus-Weil-like property. Its prototype arises in the relevant infinite combinatorics (see [BinO5, Kestelman-Borwein-Ditor Theorem], [Ost3]). The setting for the theorem is that of the Displacements Theorem (Th. 4 above), a key ingredient of which is the Kemperman property, a weak Steinhaus-Weil-like property. So Theorem 5 establishes the equivalence of a strong and a weak Steinhaus-Weil-like property in the presence of additional topological restrictions on the relevant refinement topology: invariance under shift, localization and some analyticity (namely, a weak base of analytic sets). We raise and leave open the question as to whether the three topological restrictions listed above are minimal here.

Theorem 5 (Fine Topology Shift Theorem). In a topological group under the topology of $d^L_L$, let $\mathcal{D}$ be a topology refining $d^L_L$ and having the following properties:

(i) $\mathcal{D}$ is shift-invariant: $x\mathcal{D} = \mathcal{D}$ for all $x$;
(ii) ‘Localization property’: $H \setminus \text{int}_\mathcal{D}(H) \in \mathcal{B}_0(\mathcal{D})$ for $H \in \mathcal{B}(\mathcal{D})$;
(iii) the (left) ‘Kemperman property’: for $1_G \in U \in \mathcal{D}$ there is $\delta = \delta_U > 0$ with

\[ U \cap (tU) \in \mathcal{B}_+(\mathcal{D}) \quad (||t|| < \delta); \]
(iv) \( \mathcal{D} \) is a strong generalized Gandy-Harrington topology: modulo \( \mathcal{B}_0(\mathcal{D}) \)

\( \mathcal{D} \) each \( \mathcal{B}(\mathcal{D}) \) set is analytic under \( d^G_R \), so that \( \mathcal{D} \) is a Baire space.

Then, for \( z_n \to 1_G \) (“null sequence”) and \( A \in \mathcal{B}_+(\mathcal{D}) \), for quasi all \( a \in A \) there is an infinite set \( \mathbb{M}_a \) such that

\[
\{ z_m a : m \in \mathbb{M}_a \} \subseteq A.
\]

**Proof of Theorem 5.** Since the asserted property is monotonic, we may assume by the strong Gandy-Harrington property that \( A \) is analytic in the topology of \( d^G_R \). So write \( A = K(I) \) with \( K \) upper-semicontinuous and single-valued. Below, for greater clarity we write \( B(x, r) \) for the open \( r \)-ball centered at \( x \). For each \( n \in \omega \) we find inductively integers \( i_n \), points \( x_n, y_n, a_n \) with \( a_n \in A \), numbers \( r_n \downarrow 0, s_n \downarrow 0 \), analytic subsets \( A_n \) of \( A \), and closed nowhere dense sets \( \{ F^n_m : m \in \omega \} \) w.r.t. \( \mathcal{D} \) and \( D_n \in \mathcal{D} \) such that:

\[
K(i_1, \ldots, i_n) \supseteq a_n x_n a_n^{-1} A_n \cap A_n \in \mathcal{B}_+(\mathcal{D}),
\]

\[
K(i_1, \ldots, i_n) \supseteq a_n x_n a_n^{-1} A_n \cap A_n \supseteq D_n \cap B(y_n, s_n) \bigcup_{m \in \omega} F^n_m,
\]

\[
y_n \in B(a_n x_n, r_n) \text{ and } D_n \cap B(y_n, s_n) \cap \bigcup_{m,k<n} F^k_m = \emptyset.
\]

Assuming this done for \( n \), since \( K(i_1, \ldots, i_n) = \bigcup_k K(i_1, \ldots, i_n, k) \) is non-negligible, there is \( i_{n+1} \) with \( K(i_1, \ldots, i_n, i_{n+1}) \cap a_n x_n a_n^{-1} A_n \cap A_n \) non-negligible.

Put \( A_{n+1} := K(i_1, \ldots, i_n, i_{n+1}) \cap a_n x_n a_n^{-1} A_n \cap A_n \subseteq K(i_1, \ldots, i_{n+1}) \). As \( A_{n+1} \) is non-negligible, we may pick \( a_{n+1} \in A_{n+1} \) and \( \varepsilon(a_{n+1}, A_{n+1}) \) as in Theorem 4 above; also pick \( m(n) \) so large that \( ||z_m|| < \varepsilon(a_{n+1}, A_{n+1}) \) for \( m \geq m(n) \) and that for \( x_{n+1} := a_{n+1} z_m^{-1} a_{n+1}^{-1} \) also \( ||x_{n+1}|| \leq 2^{-n} \). Then

\[
K(i_1, \ldots, i_{n+1}) \supseteq a_{n+1} x_{n+1} a_{n+1}^{-1} A_{n+1} \cap A_{n+1} \in \mathcal{B}_+(\mathcal{D}).
\]

So by the Banach Category Theorem, for some \( D_{n+1} \in \mathcal{D} \) and some positive \( r_{n+1} < r_n / 2 \)

\[
K(i_1, \ldots, i_{n+1}) \supseteq a_{n+1} x_{n+1} a_{n+1}^{-1} A_{n+1} \cap A_{n+1} \supseteq D_{n+1} \cap B(a_{n+1} x_{n+1}, r_{n+1}) \bigcup_{m \in \omega} F^{n+1}_m,
\]

for some closed nowhere dense sets \( \{ F^{n+1}_m : m \in \omega \} \) of \( \mathcal{D} \). Since the set

\[
\bigcup_{m,k<n+1} F^k_m
\]

is closed and nowhere dense, there is \( y_{n+1} \in D_{n+1} \cap B(a_{n+1} x_{n+1}, r_{n+1}) \) and positive \( s_{n+1} < s_n / 2 \) so small that \( B(y_{n+1}, s_{n+1}) \subseteq B(a_{n+1} x_{n+1}, r_{n+1}) \) and \( D_{n+1} \cap B(y_{n+1}, s_{n+1}) \cap \bigcup_{m,k<n+1} F^k_m = \emptyset \). So

\[
D_{n+1} \cap B(a_{n+1} x_{n+1}, r_{n+1}) \bigcup_{m \in \omega} F^{n+1}_m \supseteq D_{n+1} \cap B(y_{n+1}, s_{n+1}) \bigcup_{m \in \omega} F^{n+1}_m,
\]

19
completing the induction.

By the Analytic Cantor Theorem [Ost1, Th. AC, Section 2], there is \( t \) with 
\[
\{ t \} = K(i) \cap \bigcap_n B(y_n, s_n) \subseteq \bigcap_n a_n x_n a_n^{-1} A_n \cap A_n.
\]
So \( t \in A \). Fix \( n \); then \( t \notin \bigcup_{m \in \omega} F^m_n \) (since \( D_{m+1} \cap B(y_{m+1}, s_{m+1}) \cap \bigcup_{k < m} F^k_n = \emptyset \) for each \( m \)), and so \( t \in T \) and
\[
t \in D_n \cap B(y_n, s_n) \setminus \bigcup_{m \in \omega} F^m_n \subseteq a_n x_n a_n^{-1} A_n \cap A_n \subseteq K(i_1, \ldots, i_n) \subseteq A.
\]
As \( t \in a_{n+1} x_{n+1} a^{-1}_{n+1} A_{n+1}, a_{n+1} x_{n+1} a^{-1}_{n+1} t = z_{m(n)} t \in A_{n+1} \subseteq A \). So \( \{ z_{m(n)} t : n \in \omega \} \subseteq A \).

Now \( d_R^G(a_n x_n, t) \leq d_R^G(a_n x_n, y_n) + d_R^G(y_n, t) \to 0 \), so \( a_n \to t \), since \( x_n \to 1_G \).

\[ \square \]

**Corollary 2.** In the setting of Theorem 5 above, the sets of \( \mathcal{B}_+(\mathcal{D}) \) have the Steinhaus-Weil property (§1).

**Proof** (cf. [Sol1, Th. 1(ii)], [BinO4, Th. 6.5]). Otherwise, for some set \( A \in \mathcal{B}_+(\mathcal{D}) \) we may select \( z_n \notin AA^{-1} \) with \( ||z_n|| < 1/n \). Then there are \( a \in A \) and a subsequence \( m(n) \) with \( z_{m(n)} a \in A \); so \( z_{m(n)} \in AA^{-1} \), a contradiction.

\[ \square \]

6 Complements

1. **Weil topology** ([Wei, Ch. VII, §31], cf. [Hal, Ch. XII §62]). We recall that for \( G \) a group with a \( \sigma \)-finite left-invariant measure \( ||.|| \) on a \( \sigma \)-ring \( \mathcal{M} \) of left-invariant sets and \( (x, y) \mapsto (x, xy) \) measurability-preserving, the **Weil topology** is generated by the family of pseudo-norms

\[
||g||_E := |gE \triangle E|,
\]
for \( E \in \mathcal{M}_+ \) (with \( \mathcal{M}_+ \) the family of measurable sets with finite positive measure), so that \( ||g||_E \leq |E| \). Provided the pseudo-norms are **separating** (i.e. \( ||g||_E > 0 \) for any \( g \neq 1_G \) and some \( E \in \mathcal{M}_+ \) as in (iii) above), \( G \) is a topological group under the Weil topology [Hal, 62E]; equivalently, the topology is generated by the neighbourhood base \( \mathcal{N}_1 := \{ DD^{-1} : 1_G \in D \in \mathcal{M}^+ \} \), reminiscent of the Steinhaus-Weil Theorem. The proof relies
on a kind of fragmentation lemma (see [BinO8]). That in turn depends on Fubini’s Theorem [Hal, 36C], via the average theorem [Hal, 59.F]:

\[
\int_G |g^{-1}A \cap B| dg = |A| \cdot |B^{-1}| \quad (A, B \in \mathcal{M}),
\]

\( (g = ab^{-1} \text{ iff } g^{-1}a = b) \), and may be interpreted as demonstrating the continuity at 1_G of \( ||.||_E \) under the density topology.

2. **Steinhaus-Weil property of a Borel measure.** In a locally compact group \( G \), the family \( \mathcal{M}_+(\mu) \) of finite non-null measurable sets of a Borel measure \( \mu \) on \( G \) fails to have the Steinhaus-Weil property iff there are a null sequence \( z_n \to 1_G \) and a non-null compact set \( K \) with \( \lim_n \mu(t_nK) = 0 \), as observed by Mospan [Mos] (in \( \mathbb{R} \)). Equivalently, this is so iff the measure \( \mu \) is not absolutely continuous with respect to Haar measure – cf. [Sim] and [BinO8].

3. **Regular open sets.** Recall that \( U \) is regular open if \( U = \text{int}(\text{cl}U) \), and that \( \text{int}(\text{cl}U) \) is itself regular open; for background see e.g. [GivH, Ch. 10], or [Dug, Ch. 3 Problems, Section 4 Q22]. For \( \mathcal{D} = \mathcal{D}_B \) the Baire-density topology of a normed topological group, let \( \mathcal{D}_B^{RO} \) denote the regular open sets. For \( D \in \mathcal{D}_B^{RO} \), put

\[
N_D := \{ t \in G : tD \cap D \neq \emptyset \} = DD^{-1}, \quad \mathcal{N}_1 := \{ N_D : 1_G \in D \in \mathcal{D}_R \};
\]

then \( \mathcal{N}_1 \) is a base at \( 1_G \) (since \( 1_G \in C \in \mathcal{D}_R \) and \( 1_G \in D \in \mathcal{D}_R \) yield \( 1_G \in C \cap D \in \mathcal{D}_R \)) comprising \( \mathcal{T} \)-neighbourhoods that are \( \mathcal{D}_B \)-open (since \( DD^{-1} = \bigcup \{ Dd^{-1} : d \in D \} \)). We raise the (metrizability) question, by analogy with the Weil topology of a measurable group: with \( \mathcal{D}_B \) above replaced by a general density topology \( \mathcal{D} \) on a group \( G \), when is the topology generated by \( \mathcal{N}_1 \) on \( G \) a norm topology? Some indications of an answer may be found in [ArhT, §3.3]. We note the following plausible answer: if there exists a separating sequence \( D_n \), i.e. such that for each \( g \neq 1_G \) there is \( n \) with \( ||g||_{D_n} = 1 \), then

\[
||g|| := \sum_n 2^{-n} ||g||_{\bar{D}_n}
\]

is a norm, since it is separating and, by the Nikodym property, \( (D \cap g^{-1}D) = g^{-1}(gD \cap D) \in \mathcal{B}_0 \).

4. **The Effros Theorem** asserts that a transitive continuous action of a Polish group \( G \) on a space \( X \) of second category in itself is necessarily ‘open’, or more accurately is microtransitive (the (continuous) evaluation map \( e_x : g \mapsto g(x) \) takes open nhds \( E \) of \( 1_G \) to open nhds that are the orbit sets \( E(x) \) of \( x ) \). It
emerges that this assertion is very close to the shift-compactness property: see [Ost6]. The Effros Theorem reduces to the Open Mapping Theorem when $G, X$ are Banach spaces regarded as additive groups, and $G$ acts on $X$ by way of a linear surjection $L : G \to X$ via $g(x) = L(g) + x$. Indeed, here $e_0(E) = L(E)$. For a neat proof, choose an open neighbourhood $U$ of 0 in $G$ with $E \supseteq U - U$; then $L(U)$ is Baire (being analytic) and non-meagre (since $\{L(nU) : n \in N\}$ covers $X$), and so $L(U) - L(U) \subseteq L(E)$ is an open nhd of 0 in $X$.

5. **Amenability at 1.** Solecki defines $G$ to be amenable at 1 if given $\mu_n \in \mathcal{P}(G)$ with $1_G \in \text{supp}(\mu_n)$ there are $\nu$ and $\nu_n$ in $\mathcal{P}(G)$ with

$$\nu_n * \nu(K) \to \nu(K) \quad (K \in \mathcal{K}(G)).$$

(The origin of the term may be traced to a localization, via the restriction of supports to contain $1_G$, of a Reiter-like condition [Pat, Prop. 0.4] characterizing amenability itself.) It is proved in [Sol2, Th. 1(ii)] that, in the class of Polish groups $G$ that are amenable at $1_G$, the Steinhaus-Weil property holds for universally measurable sets that are not left-Haar-null; this includes Polish abelian groups [Sol2, Prop. 3.3]. The relativized notion of subcontinuity: on a compact $K$ along a null sequence $\{t_n\}$ (which requires some subsequence $\mu(t_{m(n)}K)$ to be bounded away from 0, provided $\mu(K) > 0$) yields a connection to amenability at $1_G$, which we explore elsewhere [BinO8].

6. **Haar-null and left-Haar-null.** The two families coincide in Polish abelian groups, and in locally compact second countable groups (where they also coincide with the sets of Haar measure zero – by an application of the Fubini theorem). The former family, however, is in general smaller; indeed, (universally measurable) non-Haar-null sets need not have the Steinhaus-Weil property, whereas the (universally measurable) non-left-Haar-null sets do – see [Sol2].

7. **Left-Haar-null Kemperman property.** We note, as this is thematic, that the family of (universally measurable) non-left-Haar-null sets has the left Kemperman property [BinO8, Cor. 2].

8. **Beyond local compactness: Haar category-measure duality.** In the absence of Haar measure, the definition of left-Haar-null subsets of a topological group $G$ requires $\mathcal{U}(G)$, the universally measurable sets – by dint of the role of the totality of (probability) measures on $G$. The natural dual of $\mathcal{U}(G)$ is the class $\mathcal{U}_G(G)$ of universally Baire sets, defined, for $G$ with a Baire topology, as those sets $B$ whose preimages $f^{-1}(B)$ are Baire in any compact Hausdorff space $K$.
for any continuous $f : K \to G$. Initially considered in [FenMW] for $G = \mathbb{R}$, these have attracted continued attention for their role in the investigation of axioms of determinacy and large cardinals – see especially [Woo]; cf. [MarS].

Analogously to the left-Haar-null sets, define in $G$ the family of left-Haar-meagre sets, $\mathcal{HM}(G)$, to comprise the sets $M$ coverable by a universally Baire set $B$ for which there are a compact Hausdorff space $K$ and a continuous $f : K \to G$ with $f^{-1}(gB)$ meagre in $K$ for all $g \in G$. These were introduced, in the abelian Polish group setting with $K$ metrizable, by Darji [Dar], cf. [Jab], and shown there to form a $\sigma$-ideal of meagre sets (co-extensive with the meagre sets for $G$ locally compact); as $\mathcal{HM}(G) \subseteq B_0(G)$, the family is not studied here.

9. **Non-separability.** The links between the Effros theorem above, the Baire theorem and the Steinhaus-Weil theorem are pursued at length in [Ost6]. There, any separability assumption is avoided. Instead sequential methods are used, for example shift-compactness arguments.

10. **Metrizability and Christensen’s Theorem.** An analytic topological group is metrizable; so if also it is a Baire space, then it is a Polish group [HofT, Th. 2.3.6].

11. **Strong Kemperman property: qualitative versus quantitative measure theory.** We note that property (iv) of Theorem 1 corresponds to the following qualitative, linear Lebesgue-measure property, which we may name the strong Kemperman property (see [Kem], [Kuc, Lemma 3.7.2]):

   (iv)$^*$ for $0 \in U \in \mathcal{D}_\mathcal{L}$ there is $\delta > 0$ such that for all $|t| < \delta$

   $$|U \cap (t + U)| \geq \varepsilon.$$

   This is connected with the continuity of a Weil-like group norm on $(\mathbb{R}, +)$. Indeed, since

   $$|U \cap (t + U)| = |U| - |U \triangle (t + U)|/2,$$

   the inequality above is equivalent to

   $$||t||_U := |U \triangle (t + U)| \leq 2(|U| - \varepsilon).$$

   The latter holds for any $0 < \varepsilon < |U|$ and for sufficiently small $t$, by the continuity of the norm $||t||_U$.
